<p>(54) Title: CATALYTIC ASYMMETRIC AMINOHYDROXYLATION OF OLEFINS WITH CARBAMATES</p>		
<p>(57) Abstract</p> <p>β-Hydroxyamines and β-hydroxycarbamates are synthesized from olefin substrates by means of a catalyzed asymmetric addition reaction. The addition reaction is catalyzed by osmium and is co-catalyzed by chiral ligands. The chiral ligands, in addition to being co-catalysts with the osmium, also serve to direct the addition reaction regioselectively and enantioselectively. Divalent ligands are preferred over monovalent ligands because of their enhanced regio- and enantio-selectivity. Carbamates are employed as an oxidant nitrogen source for the production of β-hydroxysulfonamides. Excellent yields and enantiomeric efficiencies are achieved with co-solvents containing 50/50 (v/v) mixtures of water and organic solvent. The performance of the reaction is further enhanced by omitting the addition silver or mercurial salts conventionally employed in asymmetric aminohydroxylation additions to olefins performed in neat or substantially neat solvents. β-Hydroxyamines are then obtained by deprotecting the corresponding β-hydroxycarbamate.</p>

CATALYTIC ASYMMETRIC AMINOHYDROXYLATION
OF OLEFINS WITH CARBAMATES

Specification

5

Field of Invention:

The invention relates to the regio-selective and enantio-selective conversion of olefins to β -hydroxyamines and β -hydroxycarbamates. More particularly, the invention relates to catalytic asymmetric additions or aminohydroxylations of olefins and other unsaturated substrates using carbamate as an oxidizing agent in the presence of an osmium catalyst and a chiral ligand.

15

Background:

Over the past 20 years, separate and distinct synthetic methodologies have been developed by Sharpless et al. for the vicinal hydroxyamination of olefins. There are three major groups of oxyamination procedures which produce aminoalcohols (Sharpless et al. *J. Am. Chem. Soc.* **1975**, 97, 2305; Sharpless et al. *J. Org. Chem.* **1978**, 43, 2628; Sharpless et al. *J. Org. Chem.* **1980**, 45, 2257), hydroxysulfonamides (Sharpless et al. *J. Org. Chem.* **1976**, 41, 177; Sharpless et al. *J. Org. Chem.* **1978**, 43, 2544; Sharpless et al. *J. Org. Chem.* **1979**, 44, 1953; Sharpless et al. *Org. Syn.* **1980**, 61, 85) or hydroxycarbamates (Sharpless et al. *J. Am. Chem. Soc.* **1978**, 100, 3596; Sharpless et al. *J. Org. Chem.* **1980**, 45, 2710; Sharpless et al. U.S. Patent No.'s 4,871,855; 4,965,364; 5,126,494; EP 0 395 729). Each oxyamination procedure has unique reaction conditions and includes variations in solvents, auxiliary salts,

- 2 -

nucleophiles, temperature, stoichiometric v. catalytic amounts of osmium species and stoichiometric v. catalytic amounts of ligand. Each procedure is highly dependant on the nature of the substrate and possesses unique properties which afford different yields, chemoselectivities, stereoselectivities, regioselectivities and enantioselectivitive outcomes.

1. Aminoalcohols

The first reported oxyamination procedure (Sharpless et al. *J. Am. Chem. Soc.* **1975**, 97, 2305) generated aminoalcohols from mono and di substituted olefins, using stoichiometric quantities of a tri-oxo(*tert*-butylimido)osmium species. The procedure required reductive cleavage of the osmate ester which was performed with lithium aluminum hydride and afforded tertiary vicinal aminoalcohols. Yields were good to excellent, but in some cases, the side product vicinal diol was formed as an undesired by-product. The stereochemistry of addition, in methylene chloride or pyridine, was exclusively *cis* (Sharpless et al. *J. Org. Chem.* **1978**, 43, 2628). In addition, the carbon-nitrogen bond formed was, in every case, at the least substituted olefinic carbon atom. Di and tri-substituted olefins reacted much slower with the generated imido reagent than with monosubstituted alkenes; tetrasubstituted alkenes yielded only the corresponding diol. However, by using a coordinating solvent such as pyridine, higher yields and higher ratios of aminoalcohol to diol were reported. Sharpless et al. *J. Org. Chem.* **1980**, 45, 2257; Sharpless et al. *J. Org. Chem.* **1976**, 41, 177; Sharpless et al. *J. Org. Chem.* **1978**, 43, 2544.

- 3 -

2. Hydroxysulfonamides

Sharpless et al. first demonstrated that hydroxysulfonamides could be obtained using either stoichiometric or catalytic amounts of 1% osmium tetroxide in the presence of 1.5 - 5 equivalents of Chloramine-T trihydrate ($\text{TsSO}_2\text{NClNa} \cdot 3\text{H}_2\text{O}$, Ts = tosylate; commercially obtained) to effect cis addition of a hydroxyl (OH) and an arylsulfonamide moiety ($\text{Ar-SO}_2\text{NH}$) across a mono or disubstituted olefinic linkages (Sharpless et. al. *J. Org. Chemistry* **1976**, 41, 177).

Two procedures were developed to effect hydroxyamination of olefins using sulfonamides. (Sharpless et al. *Org. Syn.* **1980**, 61, 85). The first procedure used phase transfer catalysis conditions at 55-60 °C with 1% OsO_4 , 1:1 v/v, 0.20 Molar $\text{CHCl}_3/\text{H}_2\text{O}$, and benzyltriethylammonium chloride as the phase transfer catalyst. The chloramine T-trihydrate ($\text{TsSO}_2\text{NClNa} \cdot 3\text{H}_2\text{O}$) was either added directly or formed *in situ* in water; this solution was then directly used in the phase transfer mixture. The *in situ* procedure, for generating the chloramine salts, involved stirring a suspension of the arylsulfonamide with an equivalent of sodium hypochlorite (Clorox) until a homogenous solution was obtained. The yields were comparable with those obtained with isolated chloramine salts and the procedure was found most effective for monosubstituted and 1,2 disubstituted olefins. The phase transfer method, however, gave poor results with trisubstituted and 1,1-disubstituted olefins and the procedure did not succeed with diethyl fumarate

- 4 -

and 2-cyclohexen-1-one. Sharpless et al. *J. Org. Chem.* **1978**, 43, 2544.

A second procedure was carried out in tert-butyl alcohol at 55- 60 °C with 1% OsO₄, silver nitrate

5 (with or without) and commercially obtained chloramine T-trihydrate (TsSO₂NClNa·3H₂O) which provided the only source of water. The procedure did not succeed with tetramethylethylene and cholesterol, and negative results were found with most hindered
10 tri- and tetrasubstituted olefins. Sharpless et. al. *J. Org. Chemistry* **1976**, 41, 177; Sharpless et al. *Org. Syn.* **1980**, 61, 85. The addition of divalent metal salts such as AgNO₃ and Hg(NO₃)₂ improved some reactions, however, other reactions suffered
15 deleterious effects from the addition of the metal salts. Sharpless et al. *J. Org. Chem.* **1978**, 43, 2544; Sharpless et. al. *J. Org. Chemistry* **1976**, 41, 177.

Further elaboration on either procedure showed that other sulfonamide derivatives (ArSO₂NClNa) could
20 be successfully employed in addition to chloramine T, where Ar = phenyl, o-tolyl, p-chlorophenyl, p-nitrophenyl, and o-carboalkoxyphenyl. Sharpless et al. *J. Org. Chem.* **1978**, 43, 2546.

Neither the phase transfer catalyst or tert-butyl alcohol procedures succeeded with tetramethyl
25 ethylene, 2,3-dimethyl-2-octene, diethyl fumarate, or 2-cyclohexen-1-one. Negative results were also obtained with most hindered tri- and tetrasubstituted olefins. Herranz E., MIT Ph.D. Thesis, **1979**, 33.

30 Solvent conditions for the synthesis of the hydroxysulfonamides included organic solvents such as acetonitrile, tert-butyl alcohol, isopropyl alcohol and chloroform which was in contact with the aqueous phase in the phase transfer catalyst procedure.

- 5 -

The tert-butyl alcohol procedure (including other solvents used) was not run with added water; the phase transfer catalyst (PTC) procedure required a biphasic mixture of 1:1 v/v chloroform/water. Recently, however, an improvement was reported which used a 1:1 ratio of organic solvent to water in a homogeneous, rather than a biphasic solution or organic solvent with small amounts of water. These conditions were found to provide optimum enantioselectivity, regioselectivity and improved yields from either the previously described t-butyl alcohol or PTC conditions. Sharpless et al. *Angew. Chemie Intl Ed.* **1996**, 35, 451.

The use of chiral ligands with sulfonamides provides enantioselectivity and has been observed to both accelerate and decelerate the rate of catalysis. The hydroxysulfonamide process is a stereoselective cis process. The presence of ligands also has a dramatic effect on the regioselectivity. In a study with no ligand present with methyl cinnamate, the two regioisomers were present in a 2:1 ratio. With the addition of ligand, the ratio was improved to 5:1 or greater. Another positive effect of the ligand was its ability to suppress formation of diol by-product. *Angew. Chemie Intl Ed.* **1996**, 35, 451.

Preferred ligands for use with sulfonamides have included the use of monovalent cinchona alkaloids or the bivalent phthalazine based, commercially available (DHQ)₂PHAL and (DHQD)₂PHAL alkaloids.

Sharpless et al. *Angew. Chemie Intl Ed.* **1996**, 35, 451.

Temperature conditions for the hydroxysulfonamide asymmetric aminohydroxylations have varied from 60 °C to 25 °C for reactions

- 6 -

including sulfonamides, auxiliary salts, ligands, phase transfer catalysts and stoichiometric or catalytic osmium species, primarily in organic solvents with small amounts of water. Recently, it has been shown that temperature can be lowered to 0 °C while running the reaction, to obtain product by filtration; many hydroxysulfonamides tend to be highly crystalline Sharpless et al. *Acta Chemica Scandinavica* **1996** in press.

Cleavage of the sulfonamides, to free aminoalcohols, have been accomplished via standard deprotection conditions including dissolving metals (Na, NH₃; Sharpless et al *J. Org. Chem* **1976**, *41*, 177) and HBr, acetic acid and phenol (Fukuyama et al. *Tetrahedron Lett.* in press).

3. Hydroxycarbamates

A drawback with the hydroxysulfonamide procedure was that cleavage conditions were too strong for some substrates. The use of carbamates to protect the nitrogen, however, provided a methodology which avoided the use of harsh acids or reducing deprotection problems found with hydroxysulfonamides (Sharpless et al. *J. Am. Chem. Soc.* **1978**, *100*, 3596; Sharpless et al. *J. Org. Chem.* **1980**, *45*, 2710; Sharpless et al. *Org. Syn.* **1981**, *61*, 93; Sharpless et al. U.S. Patent No.'s 4,871,855; 4,965,364; 5,126,494; EP 0 395 729).

Sharpless first demonstrated the synthesis of hydroxycarbamates with the use of N-chloro-N-argentocarbamates (Sharpless et al *J. Am. Chem. Soc.* **1978** *100*, 3596). The N-chloro-N-argentocarbamates were generated *in situ* via the addition of N-chlorosodiocarbamates and silver nitrate to a

- 7 -

solution of the olefin in acetonitrile or tert-butanol with trace amounts of water (4.5 molar equivalents based on olefin) and 1% of osmium tetroxide catalyst to generate vicinal
5 hydroxycarbamates in generally good yields. The methodology was reported to be more effective with electron deficient olefins such as dimethyl fumarate and trisubstituted olefins were reported to be less readily oxyaminated with N-chloro-N-argentocarbamates
10 than with the chloramine-T procedures (Sharpless et al. *J. Org. Chem.* **1976**, 41, 177).

Sodio-N-chlorocarbamates were always first converted to either argento or mercurio salt analogs. The addition of the AgNO_3 or $\text{Hg}(\text{NO}_3)_2$ salts, to make
15 N-chloro-N-argentocarbamates or mercurio salt analogs, was crucial for the reaction to retain its desired properties. (Sharpless et al *J. Org. Chem.*, **1980**, 45, 2711). This was in contrast to the sulfonamide conditions, where the sodio-N-chloro-sulfonamide salts could be used directly with either
20 the t-butanol or chloroform/water - phase transfer catalyst procedures (Sharpless et al. *J. Org. Chem.* **1978**, 43, 2544).

The addition of nucleophiles such as
25 tetraethylammonium acetate were also proven to be beneficial to the reaction in the procedures using the silver and mercury salts of the chloramines from carbonates. Alternatively, the reactivity and yields were enhanced by addition of excess AgNO_3 and
30 $\text{Hg}(\text{NO}_3)_2$ (over that needed to react with the NaClNCOOR salt) Sharpless et al. *J. Org Chem.* **1980**, 45, 2710.

Preferred conditions included employment of $\text{ROCONClNa} + \text{Hg}(\text{NO}_3)_2 + \text{Et}_4\text{NOAc}$ with N-chloro-N-

- 8 -

sodiocarbamates; these conditions were recommended as the best procedure for mono, di and tri substituted olefins even including some olefins unreactive in all of the various chloramine T based processes.

5 (Sharpless et al. *Org. Syn.* **1981**, 61, 93).

Among the carbamates tried, it was found that both benzyl *N*-chloro-*N*-argentocarbamate and tert-butyl *N*-chloro-*N*-argentocarbamates (or mercurio
10 analogs) were among the most effective oxidants, especially with addition of nucleophiles such as tetraethylammonium acetate. Other carbamates such as isopropyl, ethyl, menthyl and bornyl derivatives were also used, however, chemo, regio and
15 stereoselectivities were lower. Virtually no asymmetric induction was observed when chiral menthyl or bornyl derived carbamates were employed for hydroxyaminations. (Sharpless et al *J. Am. Chem. Soc.*
1978 100, 3596).

Sharpless disclosed the use of stoichiometric
20 amounts of a first generation monovalent alkaloid ligand with a tert-butyl derived *N*-chloro-*N*-argentocarbamate for hydroxyamination in a series of patent applications directed to ligand accelerated
25 catalytic asymmetric dihydroxylation. These disclosures illustrated an hydroxyamination on trans-stilbene with the use of 1.0 equivalent (stoichiometric to olefin) of monovalent DHQD-*p*-chlorobenzoate (DHQD= hydroquinidine) ligand, 1 mol %
osmium tetroxide, silver nitrate (figure) or mercuric
30 chloride (.80 equivalents; in protocol), 0.09 Molar acetonitrile (93.11 volume % acetonitrile) / water mix (6.89 volume % water) and tertbutyl derived *N*-chloro-*N*-argentocarbamate (1.45 equivalents) at 20 %C (figure) or 60 %C (protocol) for 1 hour. The

- 9 -

disclosure reported a 51% ee with a 93% yield of aminoalcohol. (Sharpless et al. U.S. Patent No.'s 4,871,855; 4,965,364; 5,126,494; EP 0 395 729).

5 In a review on *ligand accelerated catalysis*, Sharpless et al. noted that a 92% ee had been achieved in a stoichiometric reaction of trioxo- (tert-butylimido) osmium with stilbene in the presence of DHQD-CLB at ambient temperatures (Sharpless et al. *Angew. Chem. Int. Ed. Engl.* **1995**, 10 34, 1059, ref. 80 "unpublished results"); this mention did not disclose reaction conditions.

Recently, an oxyamination reaction for the hemisynthesis of taxol and analogs was reported using a tertbutyl derived N-chloro-N-argentocarbamate, 15 excess silver nitrate or other metallic salts, with the use of either catalytic or stoichiometric amounts of osmium and the addition of stoichiometric amounts of monovalent DHQD (hydroquinidine), DHQ (hydroquinine) ligands in an unsuccessful attempt to 20 influence the diastereoselectivity and the regioselectivity of the aminohydroxylation process. Solvent conditions varied from acetonitrile, toluene or pyridine, and the reactions were carried out at 4 °C to room temperature, in the dark. The study 25 reported that quinuclidine ligands had no effect on the amino alcohol yields but found that the addition of chiral tertiary amines had some beneficial effect on the yields of the various amino alcohol isomers formed. (Mangatal et al. *Tetrahedron* **1989** 45, 4177). 30 However, the two pseudoenantiomeric alkaloid ligands (i.e. DHQ-OAc and DHQD-OAc; OAc = acetate) gave a mixture of stereo and regioisomeric products. The result indicates that this particular hydroxyamination process (be it stoichiometric or

- 10 -

catalytic was unclear) had exhibited no "asymmetric" effects. The procedure can therefore not be regarded as an asymmetric aminohydroxylation.

As a whole, the prior art uses hydroxycarbamates which always run at room temperature with either argento or mercurio salt analogs, monovalent ligands, stoichiometric or catalytic osmium species and organic solvents with trace amounts of water.

(Sharpless et al. *J. Am. Chem. Soc.* **1978**, 100, 3596; Sharpless et al. *J. Org. Chem.* **1980**, 45, 2710; Sharpless et al. U.S. Patent No.'s 4,871,855; 4,965,364; 5,126,494; EP 0 395 729).

Cleavages of the hydroxycarbamates, to free aminoalcohols, are well known in the art and include mild acid or base hydrolysis and catalytic hydrogenolysis, depending on the attached functionality to the carbamate. (Greene, Protective Groups in Organic Synthesis, 1981, Wiley, 1st edn. pp. 223-249).

What is needed is an improved method for catalyzing the asymmetric aminohydroxylation of olefins using carbamate oxidants, wherein the improvement enhances the yields, enantiomeric efficiency, and the regio-selectivity while reducing material and labor costs.

Summary of Invention

The invention is directed to an improved method for converting olefinic substrates to asymmetric β -hydroxycarbamate products. The method of the invention employs an asymmetric addition reactions involving the asymmetric addition of an carbamoyl radical and a hydroxyl radical to the olefinic substrate. Enhanced yields, regioselectivity, and

- 11 -

5 enantioselectivity may be achieved according to the method of the invention. The asymmetric addition reaction is carried out in a reaction solution which includes the olefinic substrate, an osmium catalyst, a chiral ligand for enantiomerically and regioselectively directing the asymmetric addition, a carbamate, and a solvent or co-solvent. The carbamate serves as a source for the carbamoyl radical. The olefinic substrate and carbamate are present and soluble within the solvent or cosolvent in stoichiometric amounts. The osmium is present within the solvent or co-solvent in catalytic amounts.

15 One aspect of the invention is directed to the use of reaction solutions which employ solvents or co-solvents having both an organic component and an aqueous component, the aqueous component constituting 10% or more of the reaction solution on a volume basis. Reaction solutions containing 50% water by volume are preferred because peak yields and/or peak enantiomeric efficiencies are shown to be achieved with this mixture of solvents. Preferred organic components of the solvent or co-solvent include 20 acetonitrile, tert-butanol, and n-propanol.

25 Another aspect of the invention is directed to the use of only catalytic amounts of both the osmium catalyst and the chiral ligand in connection with the asymmetric β -aminohydroxylation reaction. The operable concentration range for the osmium catalyst in the reaction solution is between 0.5 mole % and 20 mole %. The preferred concentration of the osmium is within a range of 2 - 4 mole %. The operable concentration range for the chiral ligand in the

- 12 -

reaction solution is n within a range of substantially 1 mole % to 10 mole %. The preferred concentration of the osmium is approximately mole 5 mole % .

5

Another aspect of the invention is directed to the above methods for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product by asymmetric addition as described above wherein the solvent including an aqueous component of at least 10% or greater on a volume basis; and the solvent substantially lacks an ancillary metal salt. Specific ancillary metal salts which should be excluded are silver salts and mercury salts.

10

Description of Figures

Figure 1 illustrates the asymmetric aminohydroxylation of methylcinnamate to its corresponding α -hydroxy- β -ethylcarbamate.

15

Figure 2 shows the olefin substrate, hydroxycarbamate product, % ee (enantioselectivity) with the (DHQ)₂PHAL (DHQ = hydroquinine; PHAL = phthalazine) or (DHQD)₂PHAL (DHQD = hydroquinidine) ligands, % yields and time (h).

20

Figure 3 illustrates conversion of a variety of olefins with noted conditions, yields and % ee.

25

Figure 4 shows a series of preferred substrate olefins where R = hydrogen, aromatic, alkyl, heterocycles, hydroxyl substituents, esters, ethers, as appropriate for substrate.

30

5 Figure 5 illustrates a series of compatible olefins for aminohydroxylation including some 1,1 disubstituted and monosubstituted olefins with various functionalities.

10 Figure 6 illustrates a series of compatible olefins for aminohydroxylation including some monosubstituted and disubstituted olefins (cis and trans) with various functionalities.

15 Figure 7 illustrates a series of disubstituted olefins for asymmetric aminohydroxylation with various functionalities.

Figure 8 illustrates a series of monosubstituted and disubstituted olefins for aminohydroxylation with various functionalities.

20 Figure 9 illustrates the preferred ligand classes for aminohydroxylation wherein PHAL = Phalazine; DP-PHAL = diphenyl-phthalazine; DPP = diphenyl pyrazinopyridazine; PYR = pyrimidine; IND = indoline; AQN = anthraquinone; dihydroquinidyl (DHQD) and dihydroquinyl (DHQ).

25 Figure 10 illustrates additional ligands compatible for the asymmetric aminohydroxylation reaction.

30 Figure 11 illustrates the effects of water on the enantioselectivity of the asymmetric aminohydroxylation. The horizontal axis shows % water in increasing organic solvent (right side of graph; solvent used was n-propanol but acetonitrile, tert-butanol can also be used) where 0 % water (left

- 14 -

side of graph) indicates 100% organic solvent. The vertical axis shows % ee (enantioselectivity). Three substrates are shown including methyl cinnamate (dark diamond - medium dashed line), dimethylfumurate (open box - long dashed line) and cyclohexene (dark circle - short dashed line). No turnover and therefore no enantioselectivity is found at 0% water. Optimal concentration for highest enantioselectivity is approximately 50% water/50% organic solvent but can vary between 10-60% depending on substrate.

Figure 12 illustrates the effects of water on the yields of the asymmetric aminohydroxylation. The horizontal axis shows % water in increasing organic solvent (right side of graph; solvent used was n-propanol but acetonitrile, tert-butanol can also be used) where 0 % water (left side of graph) indicates 100% organic solvent. The vertical axis shows % yield. Three representative substrates are shown including methyl cinnamate (dark diamond - medium dashed line), dimethylfumurate (open box - long dashed line) and cyclohexene (dark circle - short dashed line). No turnover is found at 0% water. Optimal concentration for highest yield is approximately 50% water/50% organic solvent but can vary between 10-60% depending on substrate.

Figure 13 illustrates a molecular modeling study which was performed on both carbamate and sulfonamide osmium complexes; key intermediates in the catalytic process. The structures of N-methylsulfonyl- and N-methoxycarbonyl osmaazetidines were optimized by density functional theory (DFT) with Becke's three parameter hybrid method using LYP correlation

- 15 -

functional (B3LYP). The calculations were performed by using Gaussian 94 program¹ with LanL2DZ basis set. Due to the complexity of the chiral ligands, a simplified model was used. Models of N-methylsulfonyl- and N-methoxycarbonyl- osmaazetidines were adopted where the osmium atom was complexed with ammonia instead of the chiral ligand. The calculations show that the osmaazetidine rings have the flat conformations with no significant puckering as observed in osmaoxetanes. The osmaazetidine nitrogen is slightly pyramidised in the methylsulfonyl case. In the carbamate case, the osmaazetidine nitrogen is planar. The osmaazetidines are possible intermediates in [2+2] mechanistic pathway of the AA. Dihedral and bond angles are indicated.

Figure 14 illustrates a ball and stick view of the molecular modeling study as shown in figure 13 and performed on both carbamate and sulfonamide osmium complexes.

Figure 15 illustrates the asymmetric aminohydroxylation of aromatic vinyl phosphonate esters to their corresponding hydroxy-carbamate products with ee and yields indicated.

Figure 16 shows the olefin substrate, hydroxy-carbamate product, % ee (enantioselectivity) with the (DHQ)₂PHAL (DHQ = hydroquinine; PHAL = phthalazine) or (DHQD)₂PHAL (DHQD = hydroquinidine) ligands, % yields and time (h).

- 16 -

Figure 17 illustrates the asymmetric aminohydroxylation of $n\text{-C}_8\text{H}_{17}\text{CHCH}_2$ to the corresponding hydroxy-carbamate product with ee and yields indicated.

5

Figure 18 illustrates the aminoasymmetric conversion of vinyl cyclohexane to the corresponding hydroxy-carbamate product with ee and yields indicated using either $(\text{DHQD})_2\text{PHAL}$ (DHQD = hydroquinidine; PHAL = phthalazine) or $(\text{DHQD})_2\text{PYR}$ (DHQD = hydroquinidine; PYR = pyrimidine). The $(\text{DHQD})_2\text{PYR}$ ligand obtains a 1: 1.4 ratio of primary hydroxylated to secondary hydroxylated product (contrast to the $(\text{DHQD})_2\text{PHAL}$ ligand which obtains a 1:15 ratio primary hydroxylated to secondary hydroxylated product).

5 Detailed Description:

I. Olefin Classes

10 The asymmetric aminohydroxylation (AA) works well with three olefin classes: 1) monosubstituted *i* (table 1); 2) *cis*-disubstituted *iii* (table 1), and 3) *trans*-disubstituted *iv* olefins. The 1,1 disubstituted *ii* and trisubstituted types of olefins give only racemic or low ee's while the tetrasubstituted class, *vi*, does not provide any
15 signs of turnover.

Table I.

olefin class						
AD ee	good 30-99%	good 70-99%	poor 20-80%	excellent 90-	excellent 90-99%	variable 20-97%
AA ee range	good Ar, R, 40-80%	?	good	excellent up to 99%	?	?

20 II. Regioselectivity

High regioselectivity is one of the more useful features of the AA. The carbamate-version exhibits a strong preference for nitrogen attachment to the
25 olefinic carbon bearing an aromatic substituent or, in the case of olefins conjugated with a strong electron withdrawing group (EWG), the nitrogen is

- 19 -

strongly directed to the olefinic carbon distal to the EWG as illustrated in Scheme I.

5 The alkaloid ligand is responsible for high regioselectivity. When the ligand is omitted, there is little preference for either regioisomer. Beyond probable contributions from "binding pocket" effects, the strong regioselection phenomenon requires the operation of powerful electronic determinants.

Scheme I.

III. Mechanistic hypothesis

5

10

15

(1) The $\text{Os}=\text{N}-\text{X}$ linkage should be more polarized (especially when X is electron withdrawing) and also more reactive than the $\text{Os}=\text{O}$ linkage. The $\text{Os}=\text{N}-\text{X}$ linkage, therefore, reacts preferentially with the olefin to give osmaazetidine intermediates wherein the olefin osmium complexes have been omitted for clarity (Scheme II).

(2) Unsymmetric olefins such as cinnamate should strongly bias the insertion process favoring osmaazetidine **1i** over its regioisomer **2i**. Yet in the absence of a ligand roughly equal amounts of the regioisomeric products **1p** and **2p** (derived from **1i**

- 21 -

5 and **2i**, respectively) are produced. This is not surprising since one might predict that the much weaker Os-C bond in **2i** (*c.f.* same bond in **1i**) could easily siphon much of the reaction through intermediate **2i** (*i.e.* **2i** to **2p**) even if the concentration of **1i** were a 1000 times greater (Scheme II).

Scheme II.

- 5 (3) Intervention by the chiral ligand can dramatically change the outcome (Scheme III). The "binding pocket" effect favors formation of ligated intermediate **1i'**. In addition, rearrangement of the strong Os-C bond in **1i'** (c.f. EWG effect on M-C bond strengths) to product **1p'** is facilitated by both
- 10 steric and orbital-electronic effects mediated by the ligand. In this way the factors which had destroyed regioselectivity in the absence of the ligand are overridden, and the reaction is channeled along a single path at each point of decision: (1) 3-aza or
- 15 2-aza product; and (2) *S,R*- or *R,S*- enantiomer. Here the ligand controls both the regio- and the enantioselectivity.

Scheme III.

IV Rationale for olefin preferences

5 A quadrant mnemonic for the key *ligated* osmaazetidine intermediate **1i'** (scheme IV) provides an explanation as to why only 3 of the 6 olefin classes appear to make good AA substrates. Three of the four

10 quadrants are fairly easy to assign and to fit to the 3D-picture of the ligated osmaazetidine intermediate (Scheme IV): (1) the NE quadrant can handle a large group, it corresponds to the pseudoequatorial substituent (R_M) on the carbon bound to osmium; (2)

15 the SE quadrant is the one that presents as most crowded, supposedly due to the pseudoaxial

- 24 -

5 substituent on the carbon bond to osmium which is very close to the ligand at its point of ligation to osmium (unless it is a hydrogen atom, things rarely go well in the AD or the AA); (3) the SW quadrant, as in the AD, gives every sign of possessing a good "binding pocket" for aryl and some alkyl substituents (R_L).

10 As before, the situation in the NW quadrant is less predictable. This quadrant encompasses the pseudoaxial substituent (R_S) bound to oxygen (AD) or nitrogen (AA) which in either case is close to the oxo group on osmium which is trans to the ligating nitrogen of the ligand. Hydrogen bonding groups in
15 the rates and the enantioselectivities of the AD reaction (Sharpless et al *Chem Rev.*, 1994, 2488).

- 25 -

Scheme IV. AA mnemonic and 1i'-simple core (calculated).

5 V. Rationale for incompatibility with some olefin classes

 A difference between the AA and the AD, which has important practical implications, is the loss of two major olefin classes for the AA. (The
10 tetrasubstituted class vi, is ignored here since it is the least available class of olefins and has not been shown to work with the AA process). These are the 1,1-di- and trisubstituted classes (ii and v in the Table) which are generally very good in the AD.
15 (Recall that so far the PHAL ligands have been used almost exclusively in our AA studies so these comparisons seem merited). Most attempted AA's on 1,1-di- and trisubstituted olefins (ii and v, Table) have failed to give enantiomerically enriched
20 products, although excellent yields of racemic aminohydroxylation products have occasionally resulted.

 What is the problem for the AA with these substitution patterns? In both cases a hydrogen
25 substituent can be placed in the crucial SE quadrant. The stand-out difference between the AA and AD suggests a possible answer. The AA bears an extra

- 26 -

substituent, the one on nitrogen, and most importantly, in the key intermediates this substituent is forced to be "in close," a consequence of the great reactivity of the Os=N-group to which it is attached. In our usual quadrant analysis this "new" substituent must find a place for itself in a region which is crowded by parts of the ligand and by substituents (originating from the olefin) on the osmaazetidine.

In the ligated osmaazetidine intermediate (Scheme IV) this nitrogen substituent lies roughly due West at the boundary of the NW and SW quadrants. In spite of negotiable open space in the "up/down direction" the nitrogen substituent could perturb the entire system, especially for olefins with substituents in both the NW and SW sectors. Any perturbing effects of the imido nitrogen substituent should diminish as it becomes smaller, and this prediction is dramatically born out by the results using smaller sulfonamides (e.g. $\text{CH}_3\text{SO}_2\text{NH}_2$) and the carbamates, which are inherently much smaller than any sulfonamide near the crucial point of attachment to nitrogen.

A reason that the AA process is poor for 1,1-di- and trisubstituted olefins is due to the fact that the Os=N- group reacts first forcing the ligand to bind to the osmaazetidine, which has a hydrogen in the SW quadrant. The relevant intermediates are A and B respectively:

- 27 -

A

1,1disubstituted olefins

B

trisubstituted olefins

In either case, the nitrogen is forced to end up attached to a disubstituted carbon. The substituent on the nitrogen may destabilize the resulting ligated osmaazetidene intermediates **A** and **B** in a manner which does not occur for the analogous ligated osmaoxetanes.

While olefin classes *ii* and *v* may never enter the useful range in these AA processes, one can imagine using the electronic and binding pocket effects to create "ideal" substrates even for difficult classes, e.g.

In light of the above speculations, one might wonder why the *cis*-disubstituted olefins (*iii*) represent a successful class in the AA. These olefins are also forced to have a substituent in the NW quadrant. However, now there is only one substituent on the carbon bound to nitrogen in the key intermediate

- 28 -

related to **B** (i.e. $R_2 = H$). This will increase the conformational flexibility of the intermediate making *cis*-disubstituted olefins good candidates for the AA process.

5

Synthetic Protocols

10 NMR spectra were recorded on Bruker AMX-500, AM-300, or AM-250 instruments. The following abbreviations were used to explain the multiplicities: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; apt, apparent; b, broad; obs, obscured. IR spectra were recorded on Nicolet 205, Perkin Elmer 1600 or Galaxy 2020 series FT-IR

15 spectrophotometers. Optical rotations were recorded using a Perkin Elmer 241 polarimeter. High-resolution mass spectra (HRMS) were recorded on a VG ZAB-ZSE mass spectrometer under Fast Atom Bombardment (FAB) conditions, at the Scripps Research Institute.

20 All reactions were monitored by color change, HPLC, GC or thin-layer chromatography carried out on 0.25 mm Whatman silica gel plates (K6F-60 Å) using UV light, *p* - anisaldehyde, or 7% ethanolic phosphomolybdic acid and heat as developing agent.

25 E. Merck silica gel (60, particle size 0.040-0.063 mm) was used for flash column chromatography. Tetrahydrofuran (THF) and ethyl ether were distilled from sodium-benzophenone and methylene chloride, benzene and toluene were distilled from calcium

30 hydride. All reagents were obtained from Aldrich Chemical Co. Inc. unless otherwise noted. Solvents used for workup, chromatography, and recrystallizations were reagent grade from Fisher Scientific and were used as received.

- 29 -

Chloramine sodium salt preparation

Procedure as adapted from Campbell et al. *Chem. Rev.*, 1978, 78, 65.

5

General asymmetric aminohydroxylation conditions:

10 To a solution of NaOH (3.05 equivalents) in 0.13 Molar equivalent of water to olefin is added desired carbamate (3.10 equivalents). The resulting solution is stirred at room temperature for 10 min and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical) is added dropwise. The above solution is stirred for another 10 min and then 0.13 Molar
15 equivalent of *n*-propanol (*t*-butanol or acetonitrile can be substituted) and (DHQ)₂-PHAL (0.05 equivalents, 5 mol%; DHQD ₂-PHAL obtains antipode) are added to form a homogeneous solution. The reaction mixture is immersed in a room temperature
20 bath and added substrate olefin (1 equivalents) and K₂OsO₂(OH)₄ (0.04 equivalents, 4 mol%) are then added. The reaction is stirred for 45 min with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite;
25 the phases are separated, and the aqueous phase was extracted with ethyl acetate. The combined organic extracts are washed with water and brine, dried over MgSO₄ and the solvent concentrated to give the crude product. Flash chromatography of this material
30 provides the hydroxycarbamate product.

Solvent Variations:

Preferred solvents include acetonitrile, *n*-propanol, *tert*-butanol.

- 30 -

Suitable solvents include methanol, ethanol, n-butanol, n-pentanol, 2-Propanol, 2-Butanol, tert-butanol, ethylene glycol; nitriles: acetonitrile, propionitrile; ethers: tetrahydrofuran, diethyl ether, tert. butyl methyl ether, dimethoxyethane, 1,4-dioxane; miscellaneous: dimethyl formamide, acetone, benzene, toluene, chloroform, methylene chloride.

10 **Percent Water/Organic Solvent Variations**

Two key points are that the ee and especially the yields are lower in the low water range (see figures 11 and 12). No reaction is seen with only 2 to 4 equiv of water present which must be much less than 0.1% water. These same "minuscule" amounts of water" conditions work great for the silver and mercury salts of the N-chlorocarbamates in the old catalytic aminohydroxylation process with no chiral ligands present.

20 **Solvent Concentration Variations,**

In its present form the process starts to give lower selectivities for some substrates when the concentration of olefin (which of course prescribes the standard concentration of all the other species) gets much above 0.1 molar.

Ligand Variations:

30 The ligand can range from ca. 1 to 10 mol % (less is appropriate for lower temperatures; eg. 1% might be enough at 0 °C and 10 % would probably be needed to keep the % ee at reasonable levels if the temperature reaches 35 or 40 °C. In practice, the molarity of the ligand matters and the amount of ligand needed to

- 31 -

realize the "ceiling ee" scales directly with the reaction concentration (ie if twice the volume of solvent is used, then the mol% of ligand added must also double to keep its molarity constant and correspondingly if the reaction is run twice as concentrated as usual (see general recipe below) then half of the usual mol % ligand gives the needed ligand molarity). Because the crucial binding of the ligand is an extremely rapid bimolecular process, the equilibrium constant is highly sensitive to temperature which is why the molarity of ligand needed, increases rapidly with temperature.

Osmium Variations:

The amount of Os catalyst can range from 0.5% (probably even less in the very best cases, and in any case the number will drop as the process is further improved) to 10 or even 20%. The general procedure conditions uses 4% to have fast reaction times, but 2% is good for most cases. The high loadings of 20%, for example, is needed to achieve reasonable rates with very poor substrates (this conclusion follows from the extensive experience by us and others with the AD, where in desperate situations 20 or more % Os catalyst is needed.

Temperature Variations:

For most cases, the carbamate AA process is run between 10 and 25 degrees C. There may be cases where 0 degrees - up to 35 to 40 degrees may be advantageous depending on substrate.

Syntheses of a Representative Set of Hydroxycarbamates:

Synthesis of Compound 1

To a solution of NaOH (0.112 g, 3.05 mmol) in 7.5 mL of water was added ethyl carbamate (0.276 g, 3.10 mmol). The resulting solution was stirred at room temperature for 10 min and then *t*-butyl hypochlorite (0.331 g, 3.05 mmol; Aldrich Chemical) was added dropwise. The above solution was stirred for another 10 min and then 7.5 mL of *n*-propanol and (DHQ)₂-PHAL (40 mg, 0.05 mmol, 5 mol%) were added to form a homogeneous solution. The reaction mixture

- 33 -

was immersed in a room temperature bath and added methyl cinnamate (0.162 g, 1 mmol) and $K_2OsO_2(OH)_4$ (14.7 mg, 0.04 mmol, 4 mol%) were then added. The reaction was stirred for 45 min with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (sat. 6 mL); the phases were separated, and the aqueous phase was extracted with ethyl acetate (3x5 mL). The combined organic extracts were washed with water and brine, dried over $MgSO_4$ and the solvent concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/ $CHCl_3$ /MeOH) of this material provided 0.21 g (78% yield, >99% ee) of (2*R*,3*S*) vicinal hydroxycarbamate product.

If benzyl carbamate was used, 4 mL of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

- 34 -

Synthesis of Compound 2

To a solution of NaOH (3.05 equivalents) in water
5 (0.13 Molar; based on initial olefin concentration)
was added ethyl carbamate (3.10 equivalents). The
resulting solution was stirred at room temperature
for 10 minutes and then *t*-butyl hypochlorite (3.05
10 equivalents; Aldrich Chemical Company) was added
dropwise at 0 °C. The above solution was stirred for
another 10 minutes and then *n*-propanol (0.13 Molar;
based on initial olefin concentration) and (DHQ)₂-
15 PHAL (5 mol%) were added to form a homogeneous
solution. The reaction mixture was immersed in a
room temperature bath and then 2',6'-dimethyl
cinnamate (1 equivalent; Aldrich) and K₂O₂SO₂(OH)₄ (4
20 mol%) were then added. The reaction was stirred for
45 minutes at room temperature with the color
changing from light green to light yellow, followed
by quenching by addition of aqueous sodium sulfite
25 (saturated 0.17 Molar; based on initial olefin
concentration). The phases were separated, and the
aqueous phase was extracted with ethyl acetate (3x
0.20 M volumes). The combined organic extracts were
30 washed with water and brine, dried over MgSO₄ and the
solvent was concentrated to give the crude product,
which also contained the ethyl carbamate by-product
produced upon the reduction of the excess *N*-chloro-*N*-
sodiocarbamate. Flash chromatography (6:4:1
hexane/CHCl₃/MeOH) of this material provided vicinal
hydroxycarbamate product.

- 35 -

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

5

Synthesis of Compound 3

To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-PHAL (5 mol%) were added to form a homogeneous solution. The reaction mixture was immersed in a room temperature bath and then dimethylfumarate (1 equivalent; Aldrich) and K₂OsO₂(OH)₄ (4 mol%) were then added. The reaction was stirred for 45 minutes at room temperature with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (saturated 0.17 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts were washed with water and brine, dried over MgSO₄, and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced

- 36 -

upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/CHCl₃/MeOH) of this material provided vicinal hydroxycarbamate product.

5 If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

10 **Synthesis of Compound 4**

15 To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for
20 another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-PHAL (5 mol%) were added to form a homogeneous solution. The reaction mixture was immersed in a
25 room temperature bath and then cyclohexene (1 equivalent; Aldrich) and K₂OsO₇(OH)₄ (4 mol%) were then added. The reaction was stirred for 45 minutes at room temperature with the color changing from
30 light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (saturated 0.17 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The

- 37 -

combined organic extracts were washed with water and brine, dried over MgSO_4 and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/ CHCl_3 /MeOH) of this material provided vicinal hydroxycarbamate product.

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

Synthesis of Compound 5

To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-PHAL (5 mol%) were added to form a homogeneous solution. The reaction mixture was immersed in a room temperature bath and then trans-stilbene (1 equivalent; Aldrich) and $\text{K}_2\text{OsO}_2(\text{OH})_4$ (4 mol%) were then added. The reaction was stirred for 45 minutes at room temperature with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (saturated 0.17

- 38 -

5 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts were washed with water and brine, dried over MgSO_4 and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate.

10 This is an example of a solution-to-solid and solid-to-solid entry - the work-up required simple filtration which provided the vicinal hydroxycarbamate product.

15 If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

Synthesis of Compound 6

20

25 To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-
30 PHAL (5 mol%) were added to form a homogeneous solution. The reaction mixture was immersed in a

- 39 -

room temperature bath and then 2-vinylnaphthalene (1 equivalent; Aldrich) and $K_2OsO_2(OH)_4$ (4 mol%) were then added. The reaction was stirred for 45 minutes at room temperature with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (saturated 0.17 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts were washed with water and brine, dried over $MgSO_4$ and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. This is an example of a solution-to-solid and solid-to-solid entry - the work-up required simple filtration which provided the vicinal hydroxycarbamate products.

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

Synthesis of Compound 7

70% ee, 75% yield

To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05

- 40 -

equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-
5 PHAL (5 mol%) were added to form a homogeneous solution. The reaction mixture was immersed in a room temperature bath and then 1,2-dihydronaphthalene (1 equivalent; Aldrich) and K₂OsO₂(OH)₄ (4 mol%) were then added. The reaction was stirred for 45 minutes
10 at room temperature with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (saturated 0.17 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was
15 extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts were washed with water and brine, dried over MgSO₄ and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced
20 upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/CHCl₃/MeOH) of this material provided vicinal hydroxycarbamate product.

If benzyl carbamate was used, an additional 0.25
25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added

10 dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-PHAL (5 mol%) were added to form a homogeneous

15 solution. The reaction mixture was immersed in a room temperature bath and then *trans*-diethyl 3-phenyl propenyl phosphonate (1 equivalent; Aldrich) and K₂OsO₂(OH)₄ (4 mol%) were then added. The reaction was stirred for 45 minutes at room temperature with the color changing from light green to light yellow,

20 followed by quenching by addition of aqueous sodium sulfite (saturated 0.17 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts

25 were washed with water and brine, dried over MgSO₄ and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/CHCl₃/MeOH) of this material provided vicinal

30 hydroxycarbamate product.

- 43 -

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

5 To a solution of NaOH (3.05 equivalents) in water
 (0.13 Molar; based on initial olefin concentration)
 was added ethyl carbamate (3.10 equivalents). The
 resulting solution was stirred at room temperature
 for 10 minutes and then *t*-butyl hypochlorite (3.05
 10 equivalents; Aldrich Chemical Company) was added
 dropwise at 0 °C. The above solution was stirred for
 another 10 minutes and then *n*-propanol (0.13 Molar;
 based on initial olefin concentration) and (DHQ)₂-
 PHAL (5 mol%) were added to form a homogeneous
 solution. The reaction mixture was immersed in a
 15 room temperature bath and then 1-decene (1
 equivalent; Aldrich) and K₂OsO₂(OH)₄ (4 mol%) were
 then added. The reaction was stirred for 45 minutes
 at room temperature with the color changing from
 light green to light yellow, followed by quenching by
 20 addition of aqueous sodium sulfite (saturated 0.17
 Molar; based on initial olefin concentration). The
 phases were separated, and the aqueous phase was
 extracted with ethyl acetate (3x 0.20 M volumes). The
 combined organic extracts were washed with water and
 25 brine, dried over MgSO₄ and the solvent was
 concentrated to give the crude product, which also
 contained the ethyl carbamate by-product produced
 upon the reduction of the excess *N*-chloro-*N*-
 sodiocarbamate. Flash chromatography (6:4:1
 30 hexane/CHCl₃/MeOH) of this material provided vicinal
 hydroxycarbamate product.

- 45 -

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts were washed with water and brine, dried over MgSO_4 and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/ CHCl_3 /MeOH) of this material provided vicinal hydroxycarbamate product.

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

Synthesis of Compound 13

97 %ee, ~80 % yield

To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar; based on initial olefin concentration) and (DHQ)₂-PHAL (5 mol%) were added to form a homogeneous solution. The reaction mixture was immersed in a room temperature bath and then methyl-*trans*-4-nitrocinnamate (1 equivalent) and $\text{K}_2\text{OsO}_5(\text{OH})_4$ (4 mol%)

- 48 -

were then added. The reaction was stirred for 45 minutes at room temperature with the color changing from light green to light yellow, followed by quenching by addition of aqueous sodium sulfite (saturated 0.17 Molar; based on initial olefin concentration). The phases were separated, and the aqueous phase was extracted with ethyl acetate (3x 0.20 M volumes). The combined organic extracts were washed with water and brine, dried over MgSO_4 and the solvent was concentrated to give the crude product, which also contained the ethyl carbamate by-product produced upon the reduction of the excess *N*-chloro-*N*-sodiocarbamate. Flash chromatography (6:4:1 hexane/ CHCl_3 /MeOH) of this material provided vicinal hydroxycarbamate product.

If benzyl carbamate was used, an additional 0.25 M volume of *n*-propanol was added with water to dissolve all of benzyl carbamate before adding *t*-butyl hypochlorite.

Synthesis of Compound 14

93 %cc, ~50 % yield

To a solution of NaOH (3.05 equivalents) in water (0.13 Molar; based on initial olefin concentration) was added ethyl carbamate (3.10 equivalents). The resulting solution was stirred at room temperature for 10 minutes and then *t*-butyl hypochlorite (3.05 equivalents; Aldrich Chemical Company) was added dropwise at 0 °C. The above solution was stirred for another 10 minutes and then *n*-propanol (0.13 Molar;

- 49 -

5 based on initial olefin concentration) and (DHQ)₂-
PHAL (5 mol%) were added to form a homogeneous
solution. The reaction mixture was immersed in a
room temperature bath and then ethyl cis cinnamate (1
equivalent) and K₂OsO₂(OH)₄ (4 mol%) were then added.
The reaction was stirred for 45 minutes at room
temperature with the color changing from light green
to light yellow, followed by quenching by addition of
aqueous sodium sulfite (saturated 0.17 Molar; based
10 on initial olefin concentration). The phases were
separated, and the aqueous phase was extracted with
ethyl acetate (3x 0.20 M volumes). The combined
organic extracts were washed with water and brine,
dried over MgSO₄ and the solvent was concentrated to
15 give the crude product, which also contained the
ethyl carbamate by-product produced upon the
reduction of the excess *N*-chloro-*N*-sodiocarbamate.
Flash chromatography (6:4:1 hexane/CHCl₃/MeOH) of
this material provided vicinal hydroxycarbamate
20 product.

If benzyl carbamate was used, an additional 0.25
M volume of *n*-propanol was added with water to
dissolve all of benzyl carbamate before adding *t*-
butyl hypochlorite.

What is Claimed:

1. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product by asymmetric addition of an carbamoyl radical and a hydroxyl radical to the olefinic substrate, the method being of a type which employs a reaction solution which includes a carbamate as a source of the carbamoyl radical, osmium as a catalyst, a chiral ligand for enantiomerically directing said asymmetric addition, and a solvent having an organic component, the olefinic substrate and carbamate being present and soluble in stoichiometric amounts within the solvent, the osmium being present and soluble in catalytic amounts within the solvent, the chiral ligand being present and soluble within the solvent, wherein the improvement comprises:
the solvent further including an aqueous component present at 10% or greater on a volume basis.
2. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product as described in claim 1, wherein:
the aqueous component of the solvent has a range between 10% and 90% on a volume basis.
3. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product as described in claim 2, wherein:
the organic component of the solvent is selected from the group consisting of acetonitrile, tert-butanol, and n-propanol.

- 51 -

4. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product as described in claim 2, wherein:

5 the aqueous and organic components of the solvent are each approximately 50% on a volume basis.

10 5. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product by asymmetric addition of a carbamoyl radical and a hydroxyl radical to the olefinic substrate, the method being of a type which employs a reaction solution which includes a carbamate as a source of
15 the carbamoyl radical, osmium as a catalyst, a chiral ligand for enantiomerically directing said asymmetric addition, and a solvent having an organic component, the olefinic substrate and carbamate being present and soluble at a stoichiometric concentration within
20 the reaction solution, the osmium being present and soluble within the reaction solution at a catalytic concentration within a range of substantially 0.5 mole % and 20 mole %,

 wherein the improvement comprises:

25 the chiral ligand being present and soluble within the reaction solution at a catalytic concentration within a range of substantially 1 mole % to 10 mole %.

30 6. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product as described in claim 5, wherein the catalytic concentration of the osmium is within a range of 2 - 4 mole %, and wherein:

- 52 -

the chiral ligand having a catalytic concentration of approximately mole 5 mole %.

- 5 7. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product by asymmetric addition of a carbamoyl radical and a hydroxyl radical to the olefinic substrate, the method being of a type which employs a reaction solution which includes a carbamate as a source of
- 10 the carbamoyl radical, osmium as a catalyst, a chiral ligand for enantiomerically directing said asymmetric addition, and a solvent having an organic component, the olefinic substrate and carbamate being present
- 15 and soluble at a stoichiometric concentration within the reaction solution, the osmium being present and soluble in a catalytic concentration within the reaction solution, catalytic concentration having a range of substantially 0.5 mole % and 20 mole %
- 20 wherein the improvement is further characterized by:
- the solvent further including an aqueous component present at 10% or greater on a volume basis; and
- 25 the chiral ligand being present and soluble within the reaction solution at a catalytic concentration having a range of substantially 1 mole % to 10 mole %.
- 30 8. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product as described in claim 7, wherein the osmium has a catalytic concentration with a range between approximately 2 mole % and 4 mole %, and

- 53 -

wherein the improvement is further characterized by:

5 the aqueous and organic components of the solvent each having a concentration of approximately 50% on a volume basis; and the chiral ligand being present and soluble within the reaction solution at a concentration of approximately 5 mole %.

10 9. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product by asymmetric addition of a carbamoyl radical and a hydroxyl radical to the olefinic substrate, the method being of a type which employs a reaction
15 solution which includes a carbamate as a source of the carbamoyl radical, osmium as a catalyst, a chiral ligand for enantiomerically directing said asymmetric addition, and a solvent having an organic component, the olefinic substrate and carbamate being present
20 and soluble at a stoichiometric concentration within the reaction solution, the osmium being present and soluble in a catalytic concentration within the reaction solution, catalytic concentration having a range of substantially 0.5 mole % and 20 mole %

25 wherein the improvement is further characterized by:

30 the solvent further including an aqueous component present at 10% or greater on a volume basis; and the solvent substantially lacking an ancillary metal salt.

10. An improved method for converting an olefinic substrate to an asymmetric β -hydroxycarbamate product

- 54 -

as described in claim 9, wherein the improvement is further characterized by:

the ancillary metal salt is selected from the group consisting of silver salts and mercury salts.
